

**ANSWER KEY & MARKING SCHEME · CBSE CLASS 12**

# Electrochemistry

Chemistry · Chapter 2 · Use this with the Board Paper · Companion to Quick Drill

**HOW TO USE**

Attempt the Board Paper first (closed-book, full time). Then come here. For 2-mark+ questions, compare your answer to the model. For 3-4 mark questions, also consult the **Topper Templates** below — these show the exact step-by-step structure that scores full marks per CBSE marking-scheme conventions.

**MODEL ANSWERS · BOARD PAPER**
**Section A — MCQ (1 mark each, 6 Qs)**
**Q1. Standard hydrogen electrode  $E^\circ = \text{___ V}$  (by convention). [1 mark]**

 | Ans: 0.00 V (international convention; reference for all  $E^\circ$  values).

**Q2. Faraday constant  $F = \text{___ C/mol}$ . [1 mark]**

| Ans: 96500 (precise: 96485). Charge per mole of electrons.

**Q3. Nernst equation at 298K:  $E = E^\circ - \text{___} \times \log Q$ . [1 mark]**

 | Ans:  $(0.0591/n)$ .

**Q4. Anode in a galvanic cell is the site of \_\_\_\_\_. [1 mark]**

| Ans: Oxidation (loss of electrons). Negative terminal in galvanic.

**Q5. Molar conductivity  $\Lambda_m$  with concentration: \_\_\_\_ (increases / decreases). [1 mark]**

| Ans: Decreases (counter-intuitive but true; max at infinite dilution).

**Q6. Kohlrausch's law:  $\Lambda^\circ_m = \text{___} + \text{___}$  (in symbols). [1 mark]**

 | Ans:  $v_+\lambda^\circ_+ + v_-\lambda^\circ_-$ .

**Section B — Very Short Answer (2 marks each, 4 Qs)**
**Q7. Distinguish between galvanic and electrolytic cells. [2 marks]**

| Ans: GALVANIC: spontaneous redox reaction ( $\Delta G < 0$ ,  $E^\circ > 0$ ); PRODUCES electrical energy. Example: battery, Daniell cell. Anode = NEGATIVE. ELECTROLYTIC: external source drives non-spontaneous reaction ( $\Delta G > 0$ ); CONSUMES electrical energy. Example: electrolysis, electroplating, chlor-alkali. Anode = POSITIVE (connected to + terminal of external source).

**Q8. Write Nernst equation for the cell  $\text{Zn(s)} \mid \text{Zn}^{2+}(\text{c}_1) \parallel \text{Cu}^{2+}(\text{c}_2) \mid \text{Cu(s)}$  at 298K. [2 marks]**

| Ans: Cell reaction:  $\text{Zn} + \text{Cu}^{2+} \rightarrow \text{Zn}^{2+} + \text{Cu}$  ( $n = 2$ ).  $Q = [\text{Zn}^{2+}]/[\text{Cu}^{2+}] = \text{c}_1/\text{c}_2$ .  $E_{\text{cell}} = E^\circ_{\text{cell}} - (0.0591/2) \log(\text{c}_1/\text{c}_2)$ .  $E^\circ_{\text{cell}} = +1.10\text{V}$ .

**Q9. How many coulombs are needed to deposit 1 mole of aluminium ( $\text{Al}^{3+} + 3\text{e}^- \rightarrow \text{Al}$ )? [2 marks]**

| Ans:  $\text{Al}^{3+} + 3\text{e}^- \rightarrow \text{Al}$ . Need 3 moles of electrons.  $Q = 3 \times 96500 = 289,500 \text{ C}$ .

**Q10. What is the cell notation for a galvanic cell with Zn as anode and Cu as cathode in 1M solutions? [2 marks]**

| Ans:  $\text{Zn(s)} \mid \text{Zn}^{2+}(1\text{M}) \parallel \text{Cu}^{2+}(1\text{M}) \mid \text{Cu(s)}$ . Single | separates phases; double || represents salt bridge. Anode on left, cathode on right (convention).

**Section C — Short Answer (3 marks each, 3 Qs)**
**Q11. Derive the Nernst equation at 298K for a half-cell reaction. [3 marks]**

| Ans: Step 1 — Thermodynamic:  $\Delta G = \Delta G^\circ + RT \ln Q$ . For electrochemical reactions:  $\Delta G = -nFE$ ,  $\Delta G^\circ = -nFE^\circ$ . Step 2 — Substitute:  $-nFE = -nFE^\circ + RT \ln Q$ . Step 3 — Divide by  $-nF$ :  $E = E^\circ - (RT/nF) \ln Q$ . Step 4 — At  $T = 298 \text{ K}$ ,  $(RT \ln 10 / F) = 0.0591\text{V}$ . So at 298K:  $E = E^\circ - (0.0591/n) \log Q$ . This is the Nernst equation in its working form.

**Q12. Given  $E^\circ_{\text{Ni}^{2+}/\text{Ni}} = -0.25\text{V}$  and  $E^\circ_{\text{Cu}^{2+}/\text{Cu}} = +0.34\text{V}$ , identify cathode + anode + compute  $E^\circ_{\text{cell}}$  + write cell notation. [3 marks]**

| Ans: Higher  $E^\circ =$  cathode. Cu ( $E^\circ = +0.34\text{V}$ ) is CATHODE; Ni ( $E^\circ = -0.25\text{V}$ ) is ANODE.  $E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = 0.34 - (-0.25) = +0.59\text{V}$ . Positive  $E^\circ$  confirms spontaneous galvanic direction. Cell notation:  $\text{Ni(s)} \mid \text{Ni}^{2+}(1\text{M}) \parallel \text{Cu}^{2+}(1\text{M}) \mid \text{Cu(s)}$ .

**Q13. Explain how Kohlrausch's law can be used to find  $\Lambda^\circ_m$  of weak electrolyte  $\text{CH}_3\text{COOH}$  from data on strong electrolytes. [3 marks]**

**Ans:** Direct measurement of  $\Lambda^\circ_m$  for weak electrolyte is impossible (they don't fully dissociate even at high dilution). By Kohlrausch's law, ions contribute independently at infinite dilution. So  $\Lambda^\circ_m(\text{CH}_3\text{COOH})$  can be derived from strong-electrolyte data:  $\Lambda^\circ_m(\text{CH}_3\text{COOH}) = \Lambda^\circ_m(\text{CH}_3\text{COONa}) + \Lambda^\circ_m(\text{HCl}) - \Lambda^\circ_m(\text{NaCl})$ . The ions  $\text{H}^+$  and  $\text{CH}_3\text{COO}^-$  are obtained by combining the three:  $\text{CH}_3\text{COO}^-$  (from  $\text{CH}_3\text{COONa}$ ) +  $\text{H}^+$  (from  $\text{HCl}$ ) -  $\text{Na}^+/\text{Cl}^-$  pair (from  $\text{NaCl}$ ).

**Section D — Long Answer (4 marks each, 2 Qs)**

**Q14. (a) State Faraday's two laws of electrolysis. (b) Calculate the mass of copper deposited when 0.5 A current is passed through a  $\text{CuSO}_4$  solution for 1 hour. (Atomic mass of Cu = 63.5 g/mol) [4 marks]**

**Ans:** (a) **FIRST LAW:** Mass deposited at an electrode is proportional to the quantity of electricity passed.  $m = Z \times Q = Z \times I \times t$ , where  $Z = \text{equivalent weight} / F$ . **SECOND LAW:** When the same quantity of electricity passes through different electrolytes, masses deposited are proportional to their equivalent weights:  $m_1/m_2 = E_1/E_2$ . (b)  $Q = I \times t = 0.5 \times 3600 = 1800 \text{ C}$ .  $\text{Cu}^{2+} + 2e^- \rightarrow \text{Cu}$ , so equivalent weight =  $63.5/2 = 31.75 \text{ g/eq}$ .  $m = (Q \times \text{eq.wt})/F = (1800 \times 31.75)/96500 = 57150/96500 = 0.592 \text{ g of Cu}$ . Verify: moles of  $e^- = 1800/96500 = 0.0187$ ; moles of  $\text{Cu} = 0.0187/2 = 0.00933$ ; mass =  $0.00933 \times 63.5 = 0.592 \text{ g}$  ✓

**Q15. Case study: Corrosion of iron causes losses of nearly 2-3% of global GDP annually. (a) Describe the electrochemical mechanism of rusting. (b) State THREE methods for preventing corrosion, with the principle behind each. [3 marks]**

**Ans:** (a) **Rust mechanism:** iron rusts via electrochemical process. Iron acts as **ANODE**:  $\text{Fe} \rightarrow \text{Fe}^{2+} + 2e^-$ . Oxygen at adjacent **CATHODE** sites is reduced:  $\text{O}_2 + 4\text{H}^+ + 4e^- \rightarrow 2\text{H}_2\text{O}$ .  $\text{Fe}^{2+}$  ions are further oxidised by atmospheric  $\text{O}_2$  and combine with water to form hydrated iron(III) oxide:  $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O} = \text{RUST}$ . Three requirements:  $\text{O}_2$ ,  $\text{H}_2\text{O}$ , electrolyte ( $\text{CO}_2$  dissolved in water creates carbonic acid). (b) **PREVENTION:** (1) **BARRIER coating** — paint, oil, plastic, or tin-plating physically excludes  $\text{O}_2$  and  $\text{H}_2\text{O}$ . Mechanism: physical isolation. (2) **GALVANISATION** — coat iron with zinc. Mechanism:  $\text{Zn}$  ( $E^\circ = -0.76\text{V}$ ) is more reactive than  $\text{Fe}$  ( $E^\circ = -0.44\text{V}$ ), so  $\text{Zn}$  oxidises preferentially, sacrificing itself. Protects even if scratched. (3) **CATHODIC PROTECTION** — connect a more reactive metal ( $\text{Mg}$ ,  $\text{Zn}$  block) to the iron structure. Mechanism: the connected metal oxidises instead of the iron. Used in underground pipelines, ship hulls.

**★ TOPPER ANSWER TEMPLATES**

3 TEMPLATES · MEMORISE THE FORMAT

**★ TOPPER TEMPLATE — 5-mark question: Derive Nernst equation for a half-cell + apply at non-standard concentrations**

Annual

<b>Step 1</b> [1 mark]	<b>Start from thermodynamic relationship</b>	$\Delta G = \Delta G^\circ + RT \ln Q$ (general result for any reaction at non-standard state). For electrochemical reaction, the work done is electrical: $\Delta G = -nFE$ and $\Delta G^\circ = -nFE^\circ$ . Substitute: $-nFE = -nFE^\circ + RT \ln Q$ .
<b>Step 2</b> [1 mark]	<b>Solve for E</b>	Divide both sides by $-nF$ : $E = E^\circ - (RT/nF) \ln Q$ . This is the <b>NERNST EQUATION</b> in its general form. $T$ = absolute temperature in Kelvin; $F$ = Faraday constant = 96485 C/mol; $R = 8.314 \text{ J/(mol}\cdot\text{K)}$ ; $n$ = number of electrons transferred.
<b>Step 3</b> [1 mark]	<b>Substitute room-temperature constants</b>	At $T = 298 \text{ K}$ ( $25^\circ\text{C}$ ), the constants combine: $RT/F \times \ln(10) = (8.314 \times 298 / 96485) \times 2.303 \approx 0.0591 \text{ V}$ . Substituting: $E = E^\circ - (0.0591/n) \log Q$ . This is the room-temperature working form examiners expect in numerical questions.
<b>Step 4</b> [1 mark]	<b>Apply to a specific cell</b>	For $\text{Cu}^{2+} + 2e^- \rightarrow \text{Cu}$ at $0.1 \text{ M}$ [ $\text{Cu}^{2+}$ ]: $Q = 1/[\text{Cu}^{2+}] = 1/0.1 = 10$ . $E = 0.34 - (0.0591/2) \times \log(10) = 0.34 - 0.02955 \approx 0.31 \text{ V}$ . So reducing [ $\text{Cu}^{2+}$ ] from $1\text{M}$ to $0.1\text{M}$ lowers the half-cell potential by $\sim 30\text{mV}$ .
<b>Step 5</b> [1 mark]	<b>Application — cell EMF at non-standard state</b>	For a complete cell, $E_{\text{cell}} = E^\circ_{\text{cell}} - (0.0591/n) \log Q$ where $Q$ is the cell reaction quotient. <b>EMF DROPS</b> as the reaction proceeds (products build, reactants deplete, $Q$ increases). When $E_{\text{cell}} = 0$ , the cell has reached equilibrium — no more useful work. This is the basis of all battery design + Nernst-equation calculations CBSE tests.

**COMMON LOSS OF MARKS:**

- Skipping the  $\Delta G \rightarrow -nFE$  substitution (-1 mark).
- Using  $\log$  instead of  $\ln$  without the 2.303 factor (-1 mark).
- Missing the  $(0.0591/n)$  shortcut at  $298\text{K}$  (-0.5 mark).

★ **TOPPER TEMPLATE — 4-mark question: Galvanic cell EMF computation from  $E^\circ$  values + cell notation**

90% of years

<b>Step 1</b> [1 mark]	<b>Identify cathode (higher <math>E^\circ</math>) and anode (lower <math>E^\circ</math>)</b>	Given two half-cells, both written as REDUCTION potentials. The half-cell with HIGHER $E^\circ$ (more positive reduction potential) acts as CATHODE — gets reduced. The LOWER $E^\circ$ half-cell acts as ANODE — gets oxidised. Example: $\text{Zn}^{2+}/\text{Zn}$ ( $E^\circ = -0.76\text{V}$ ) and $\text{Cu}^{2+}/\text{Cu}$ ( $E^\circ = +0.34\text{V}$ ). Cu is cathode; Zn is anode.
<b>Step 2</b> [1 mark]	<b>Compute cell EMF</b>	$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}}$ (both as REDUCTION potentials). Example: $E^\circ_{\text{cell}} = 0.34 - (-0.76) = +1.10\text{ V}$ . Positive $E^\circ_{\text{cell}}$ confirms the spontaneous direction. If $E^\circ_{\text{cell}}$ is negative, you've got the cathode/anode wrong — swap them.
<b>Step 3</b> [1 mark]	<b>Write cell notation</b>	Convention: ANODE   anode-ion (concentration)    cathode-ion (concentration)   CATHODE. The   separates phases; the    represents the salt bridge. Example: $\text{Zn(s)}   \text{Zn}^{2+}(1\text{M})    \text{Cu}^{2+}(1\text{M})   \text{Cu(s)}$ . The double-bar emphasises that the salt bridge eliminates liquid junction potential.
<b>Step 4</b> [1 mark]	<b>Identify electron flow and ion migration</b>	Electrons flow from anode (Zn) to cathode (Cu) in the external circuit. In the salt bridge, cations migrate toward the cathode half-cell; anions migrate toward the anode half-cell — completing the circuit and maintaining electrical neutrality. CBSE rewards explicit mention of both directions in 5-mark long-answers.

**COMMON LOSS OF MARKS:**

- Reversing cathode and anode (-2 marks).
- Adding  $E^\circ$  values instead of subtracting cathode minus anode (-1 mark).
- Wrong cell notation order (-0.5 mark).

★ **TOPPER TEMPLATE — 4-mark numerical: Faraday's laws — mass deposited / moles of gas evolved**

80% of years

<b>Step 1</b> [1 mark]	<b>Compute total charge Q passed</b>	$Q = I \times t$ (current in amperes $\times$ time in seconds). Example: $I = 2\text{ A}$ , $t = 30\text{ min} = 1800\text{ s}$ . $Q = 2 \times 1800 = 3600\text{ C}$ .
<b>Step 2</b> [1 mark]	<b>Compute moles of electrons (or use Faraday's law)</b>	Moles of electrons = $Q/F$ where $F = 96500\text{ C/mol}$ . Example: $3600/96500 = 0.0373\text{ mol}$ of electrons. Alternative direct route via Faraday's first law: $m = (Z \times I \times t)$ where $Z = \text{equivalent weight} / 96500$ (electrochemical equivalent).
<b>Step 3</b> [1 mark]	<b>Apply to half-reaction to find product</b>	Identify half-reaction. Example: $\text{Cu}^{2+} + 2e^- \rightarrow \text{Cu}$ means 2 moles of electrons produce 1 mole of Cu. So $0.0373\text{ mol electrons} \rightarrow 0.0373/2 = 0.0187\text{ mol Cu} = 0.0187 \times 63.5\text{ g} = 1.18\text{ g Cu}$ deposited at the cathode.
<b>Step 4</b> [1 mark]	<b>Quote final answer with units + verify</b>	1.18 g of Cu deposited. Verify: Cu equivalent weight = $63.5/2 = 31.75\text{ g/eq}$ . Mass = $(3600/96500) \times 31.75 = 1.18\text{ g}$ ✓. Always quote units (g for mass, L or mol for gas) — CBSE deducts 0.5 mark for missing units.

**COMMON LOSS OF MARKS:**

- Wrong n in moles-of-electrons step (-2 marks).
- Forgetting the half-reaction stoichiometry (-1 mark).
- Missing units (-0.5).

**MARKING SCHEME — GENERAL NOTES**

- Numerical questions: step marks for Q computation, moles of electrons, half-reaction stoichiometry, final mass with units.
- Derivation questions:  $\Delta G \rightarrow -nFE$  substitution + algebraic step + room-temperature shortcut.
- Cell EMF questions: must identify cathode/anode correctly; subtracting wrong direction loses 2 marks.
- Corrosion questions: must mention all THREE requirements ( $\text{O}_2 + \text{H}_2\text{O} + \text{electrolyte}$ ) for full marks.
